MVC Project: Multilayer Perceptron
From Forward Pass to Gradient Descent and Optimizers

Roll No: 25I-3075

National University of Computer and Emerging Sciences
Department of Computer Science
Course: Artificial Neural Networks

Abstract. This report presents a complete manual and programmatic implementation of a Multilayer Perceptron (MLP) trained on the Student Performance dataset (Tasks 1–6) and the MNIST handwritten digit dataset (Task 7). Every computation — forward propagation, MSE loss, backpropagation, gradient descent variants, and momentum-based optimizers — is derived by hand using individually assigned weights (w_1=−0.45, w_2=−0.39, w_3=−0.11, w_4=0.29, w_5=0.18, w_6=0.74, w_7=0.49, w_8=−0.49, w_9=−0.15, w_{10}=−0.66, $b^{(1)}$=−0.12, $b^{(2)}$=−0.09) and then scaled to MNIST using NumPy. The network achieves competitive test accuracy on MNIST purely through hand-implemented backpropagation without any deep learning frameworks.

Keywords: Multilayer Perceptron · Backpropagation · Gradient Descent · MNIST · Sigmoid Activation · Mini-Batch Training

1 Introduction

Neural networks are universal function approximators that learn by iteratively adjusting weight parameters to minimise a loss function. This project builds every component of an MLP from scratch in seven sequential tasks, each building directly on the previous one.

The network architecture (Table 1) uses sigmoid activations throughout and a shared bias per hidden layer — a deliberate simplification that reduces manual calculation effort while preserving all the conceptual depth of the forward and backward passes.

Table 1. Network architecture for Tasks 1–6 (Student Performance dataset).

Layer	Type	Neurons	Activation
Layer 0	Input	2	—
Layer 1	Hidden 1	2	Sigmoid σ
Layer 2	Hidden 2	2	Sigmoid σ
Layer 3	Output	1	Sigmoid σ

The dataset contains three student samples with binary pass/fail labels (Table 2).

Table 2. Student Performance dataset.

Sample	x_1 (Study Hours)	x_2 (Attendance)	y (Pass?)
$s^{(1)}$	0.2	0.8	1
$s^{(2)}$	0.9	0.4	1
$s^{(3)}$	0.1	0.2	0

2 Task 1: Forward Pass

2.1 Symbolic Equations

The forward pass computes a weighted sum followed by sigmoid activation at each layer.

Hidden Layer 1:

$$z_1^{(1)} = w_1 x_1 + w_3 x_2 + b^{(1)} \tag{1}$$
$$a_1^{(1)} = \sigma(z_1^{(1)}) = \frac{1}{1 + e^{-z_1^{(1)}}} \tag{2}$$
$$z_2^{(1)} = w_2 x_1 + w_4 x_2 + b^{(1)} \tag{3}$$
$$a_2^{(1)} = \sigma(z_2^{(1)}) \tag{4}$$

Hidden Layer 2:

$$z_1^{(2)} = w_5 a_1^{(1)} + w_7 a_2^{(1)} + b^{(2)} \tag{5}$$
$$a_1^{(2)} = \sigma(z_1^{(2)}) \tag{6}$$
$$z_2^{(2)} = w_6 a_1^{(1)} + w_8 a_2^{(1)} + b^{(2)} \tag{7}$$
$$a_2^{(2)} = \sigma(z_2^{(2)}) \tag{8}$$

Output Layer (no bias):

$$z_1^{(3)} = w_9 a_1^{(2)} + w_{10} a_2^{(2)} \tag{9}$$
$$\hat{y} = \sigma(z_1^{(3)}) \tag{10}$$

2.2 Numerical Computation for $s^{(1)}$

Using $x_1 = 0.2$, $x_2 = 0.8$, $y = 1$:

Step 1 — Hidden Layer 1:

$$z_1^{(1)} = (-0.45)(0.2) + (-0.11)(0.8) + (-0.12) = -0.0900 - 0.0880 - 0.12 = -0.2980$$
$$a_1^{(1)} = \sigma(-0.2980) = \mathbf{0.4260}$$

$$z_2^{(1)} = (-0.39)(0.2) + (0.29)(0.8) + (-0.12) = -0.0780 + 0.2320 - 0.12 = 0.0340$$
$$a_2^{(1)} = \sigma(0.0340) = \mathbf{0.5085}$$

Step 2 — Hidden Layer 2:

$$z_1^{(2)} = (0.18)(0.4260) + (0.49)(0.5085) + (-0.09) = 0.0767 + 0.2492 - 0.09 = 0.2359$$
$$a_1^{(2)} = \sigma(0.2359) = \mathbf{0.5587}$$

$$z_2^{(2)} = (0.74)(0.4260) + (-0.49)(0.5085) + (-0.09) = 0.3153 - 0.2492 - 0.09 = -0.0239$$
$$a_2^{(2)} = \sigma(-0.0239) = \mathbf{0.4940}$$

Step 3 — Output Layer:

$$z_1^{(3)} = (-0.15)(0.5587) + (-0.66)(0.4940) = -0.0838 - 0.3261 = -0.4099$$
$$\hat{y} = \sigma(-0.4099) = \mathbf{0.3989}$$

True label $y = 1$, prediction $\hat{y} = 0.3989$, error $= 0.6011$.

Table 3. Forward pass results for all three samples.

Sample	x_1	x_2	$a_1^{(1)}$	$a_2^{(1)}$	$a_1^{(2)}$	$a_2^{(2)}$	y	$\hat{y}$
$s^{(1)}$	0.2	0.8	0.4260	0.5085	0.5587	0.4940	1	0.3989
$s^{(2)}$	0.9	0.4	0.3615	0.4122	0.5441	0.4939	1	0.3995
$s^{(3)}$	0.1	0.2	0.4534	0.4748	0.5558	0.5032	0	0.3976

2.3 Forward Pass for All Samples

All predictions cluster near $\hat{y} \approx 0.40$ regardless of the true label, demonstrating that randomly initialised weights produce no meaningful discrimination.

2.4 Discussion Questions

Q1. The sigmoid activation introduces non-linearity. Without activation functions, stacking linear layers still produces a single linear transformation, preventing the network from learning non-linear decision boundaries.

Q2. All predictions are near 0.40 — the network is currently wrong for $s^{(1)}$ and $s^{(2)}$ (should be 1) and only accidentally near-correct for $s^{(3)}$. This confirms that randomly initialised weights are useless without training.

Q3. Sigmoid maps any real number to $(0, 1)$, directly interpretable as $P(y{=}1 \mid x)$. A threshold of 0.5 then yields the hard binary prediction.

3 Task 2: Loss Calculation

3.1 MSE Formula

$$\mathcal{L}_{\text{MSE}} = \frac{1}{m}\sum_{i=1}^{m}(y^{(i)} - \hat{y}^{(i)})^2 = \frac{1}{3}\Big[(1-\hat{y}^{(1)})^2 + (1-\hat{y}^{(2)})^2 + (0-\hat{y}^{(3)})^2\Big] \tag{11}$$

3.2 Numerical Computation

$$\begin{aligned}
(y^{(1)} - \hat{y}^{(1)})^2 &= (1-0.3989)^2 = (0.6011)^2 = 0.3613 \\
(y^{(2)} - \hat{y}^{(2)})^2 &= (1-0.3995)^2 = (0.6005)^2 = 0.3606 \\
(y^{(3)} - \hat{y}^{(3)})^2 &= (0-0.3976)^2 = (0.3976)^2 = 0.1581 \\
\text{SSE} &= 0.3613 + 0.3606 + 0.1581 = 0.8800 \\
\mathcal{L}_{\text{MSE}} &= \frac{0.8800}{3} = \mathbf{0.2933}
\end{aligned}$$

3.3 Discussion Questions

Q1. $\mathcal{L} = 0$ would mean every prediction equals its true label exactly. In practice this is unachievable because sigmoid asymptotically approaches 0 and 1, and real data contains noise.

Q2. $\mathcal{L} = 0.2933$ is about 29% of the maximum loss of 1.0 — moderate, reflecting uniformly uninformed predictions.

Q3. Binary Cross-Entropy penalises confident wrong predictions exponentially via $-\log(\hat{y})$, whereas MSE's quadratic penalty $(y - \hat{y})^2$ is at most 1. BCE is the theoretically correct companion to a sigmoid output for binary classification.

4 Task 3: Backpropagation

4.1 Chain Rule Foundation

Backpropagation applies the chain rule layer by layer from right to left:

$$\frac{\partial \mathcal{L}}{\partial w} = \frac{\partial \mathcal{L}}{\partial z} \cdot \frac{\partial z}{\partial w} \tag{12}$$

We define the delta (error signal) at each neuron:

$$\delta_j^{(l)} = \frac{\partial \mathcal{L}}{\partial z_j^{(l)}} \tag{13}$$

4.2 Delta Computation Rules

Output layer:

$$\delta_1^{(3)} = \frac{\partial \mathcal{L}}{\partial \hat{y}} \cdot \sigma'(z_1^{(3)}) = -2(y - \hat{y}) \cdot \hat{y}(1 - \hat{y}) \tag{14}$$

Hidden layers:

$$\delta_j^{(l)} = \left(\sum_k w_{kj}^{(l+1)} \, \delta_k^{(l+1)} \right) \cdot a_j^{(l)}(1 - a_j^{(l)}) \tag{15}$$

Weight gradient:

$$\frac{\partial \mathcal{L}}{\partial w_{ji}^{(l)}} = \delta_j^{(l)} \cdot a_i^{(l-1)} \tag{16}$$

4.3 Numerical Backpropagation for $s^{(1)}$

Step 1 — Output delta:

$$\begin{aligned} \delta_1^{(3)} &= -2(1 - 0.3989) \times 0.3989 \times (1 - 0.3989) \\ &= -2 \times 0.6011 \times 0.2398 = \mathbf{-0.2883} \end{aligned}$$

Step 2 — Gradients for w_9, w_{10}:

$$\frac{\partial \mathcal{L}}{\partial w_9} = (-0.2883)(0.5587) = \mathbf{-0.1610}$$

$$\frac{\partial \mathcal{L}}{\partial w_{10}} = (-0.2883)(0.4940) = \mathbf{-0.1424}$$

Step 3 — Hidden Layer 2 deltas:

$$\delta_1^{(2)} = ((-0.15)(-0.2883)) \times 0.5587 \times (1 - 0.5587) = 0.0432 \times 0.2466 = \mathbf{0.0107}$$

$$\delta_2^{(2)} = ((-0.66)(-0.2883)) \times 0.4940 \times (1 - 0.4940) = 0.1902 \times 0.2500 = \mathbf{0.0476}$$

Step 4 — Gradients for w_5–w_8, $b^{(2)}$:

$$\frac{\partial \mathcal{L}}{\partial w_5} = 0.0107 \times 0.4260 = \mathbf{0.0045}$$

$$\frac{\partial \mathcal{L}}{\partial w_6} = 0.0476 \times 0.4260 = \mathbf{0.0203}$$

$$\frac{\partial \mathcal{L}}{\partial w_7} = 0.0107 \times 0.5085 = \mathbf{0.0054}$$

$$\frac{\partial \mathcal{L}}{\partial w_8} = 0.0476 \times 0.5085 = \mathbf{0.0242}$$

$$\frac{\partial \mathcal{L}}{\partial b^{(2)}} = 0.0107 + 0.0476 = \mathbf{0.0582}$$

Step 5 — Hidden Layer 1 deltas:

$$\delta_1^{(1)} = ((0.18)(0.0107) + (0.49)(0.0476)) \times 0.4260 \times 0.5740 = 0.0252 \times 0.2445 = \mathbf{0.0062}$$
$$\delta_2^{(1)} = ((0.74)(0.0107) + (-0.49)(0.0476)) \times 0.5085 \times 0.4915 = -0.0154 \times 0.2499 = -\mathbf{0.0039}$$

Step 6 — Gradients for w_1–w_4, $b^{(1)}$:

$$\frac{\partial \mathcal{L}}{\partial w_1} = 0.0062 \times 0.2 = \mathbf{0.0012}$$
$$\frac{\partial \mathcal{L}}{\partial w_2} = -0.0039 \times 0.2 = -\mathbf{0.0008}$$
$$\frac{\partial \mathcal{L}}{\partial w_3} = 0.0062 \times 0.8 = \mathbf{0.0049}$$
$$\frac{\partial \mathcal{L}}{\partial w_4} = -0.0039 \times 0.8 = -\mathbf{0.0031}$$
$$\frac{\partial \mathcal{L}}{\partial b^{(1)}} = 0.0062 + (-0.0039) = \mathbf{0.0023}$$

4.4 Gradient Summary

Table 4. All 12 gradients computed for sample $s^{(1)}$.

Parameter	Current	Gradient	Parameter	Current	Gradient
w_1	-0.45	$+0.0012$	w_6	$+0.74$	$+0.0203$
w_2	-0.39	-0.0008	w_7	$+0.49$	$+0.0054$
w_3	-0.11	$+0.0049$	w_8	-0.49	$+0.0242$
w_4	$+0.29$	-0.0031	w_9	-0.15	-0.1610
w_5	$+0.18$	$+0.0045$	w_{10}	-0.66	-0.1424
$b^{(1)}$	-0.12	$+0.0023$	$b^{(2)}$	-0.09	$+0.0582$

4.5 Discussion Questions

Q1. Weights with negative gradients (w_9, w_{10}, w_2, w_4) will be increased by gradient descent; positive-gradient weights will be decreased. The largest adjustments are to the output weights w_9 and w_{10}.

Q2. The vanishing gradient problem: sigmoid derivative $\sigma'(z) = a(1-a) \leq 0.25$ at every layer. Multiplying these values layer by layer causes gradients in early layers to shrink exponentially, making them learn extremely slowly.

Q3. With 12 parameters and even 1000 discrete values each, we would need 10^{36} evaluations — more than the atoms in the observable universe. Backpropagation computes the exact gradient in $O(\text{parameters})$ time.

5 Task 4: Weight Update and Multiple Iterations

5.1 Gradient Descent Update Rule

$$w \leftarrow w - \eta \cdot \frac{\partial \mathcal{L}}{\partial w}, \qquad \eta = 0.1 \tag{17}$$

5.2 One Update Step (Iteration 1)

$$
\begin{aligned}
w_1^{\text{new}} &= -0.45 - 0.1 \times (0.0012) = \mathbf{-0.4501} \\
w_2^{\text{new}} &= -0.39 - 0.1 \times (-0.0008) = \mathbf{-0.3899} \\
w_3^{\text{new}} &= -0.11 - 0.1 \times (0.0049) = \mathbf{-0.1105} \\
w_4^{\text{new}} &= 0.29 - 0.1 \times (-0.0031) = \mathbf{0.2903} \\
b^{(1)\text{new}} &= -0.12 - 0.1 \times (0.0023) = \mathbf{-0.1202} \\
w_9^{\text{new}} &= -0.15 - 0.1 \times (-0.1610) = \mathbf{-0.1339} \\
w_{10}^{\text{new}} &= -0.66 - 0.1 \times (-0.1424) = \mathbf{-0.6458}
\end{aligned}
$$

5.3 Loss Over 5 Iterations

Table 5. MSE loss over 5 SGD iterations (sample $s^{(1)}$ only).

Iteration	MSE Loss	Decreased?
0 (initial)	0.2933	—
1	0.2911	Yes
2	0.2890	Yes
3	0.2869	Yes
4	0.2848	Yes
5	0.2829	Yes

Loss decreases consistently by approximately 0.0021 per iteration, confirming that $\eta = 0.1$ is a stable learning rate for this problem.

6 Task 5: Gradient Descent Variants

6.1 Three Variants

Batch GD: Uses all m samples per update. Stable but slow on large datasets.

SGD: Uses one sample per update ($m = 1$). Fast but noisy gradient estimates.

Mini-Batch GD:

$$\frac{\partial \mathcal{L}}{\partial w} = \frac{1}{B} \sum_{i \in \text{batch}} \frac{\partial \mathcal{L}^{(i)}}{\partial w}, \qquad B = 2 \tag{18}$$

Industry standard: balances speed and stability.

6.2 Mini-Batch Training Results

With $m = 3$, $B = 2$: $\lceil 3/2 \rceil = 2$ batches per epoch.

Q3. For MNIST ($m = 60{,}000$, $B = 32$): $\lceil 60000/32 \rceil = 1875$ updates per epoch, compared to 1 for Batch GD — 1875× more updates.

7 Task 6: Optimizers

7.1 SGD with Momentum

$$v_t = \beta v_{t-1} + (1 - \beta) \frac{\partial \mathcal{L}}{\partial w}, \qquad w \leftarrow w - \eta v_t, \qquad \beta = 0.9 \tag{19}$$

Table 6. Mini-batch training losses over 3 epochs.

Epoch	Batch	Samples	MSE Loss
1	1	$s^{(1)}, s^{(2)}$	0.3560
1	2	$s^{(3)}$	0.1592
2	1	$s^{(3)}, s^{(1)}$	0.2593
2	2	$s^{(2)}$	0.3533
3	1	$s^{(2)}, s^{(3)}$	0.2581
3	2	$s^{(1)}$	0.3483

At step 1 ($v_0 = 0$): $v_1 = 0.1 \times$ gradient.
Example for w_9:

$$v_1^{w_9} = 0.9(0) + 0.1(-0.1610) = -0.0161$$
$$w_9^{\text{new}} = -0.15 - 0.1(-0.0161) = \mathbf{-0.1484}$$

7.2 Nesterov Accelerated Gradient (NAG)

NAG computes the gradient at a lookahead position $\tilde{w} = w - \eta\beta v_{t-1}$ rather than at the current position. On step 1 ($v_0 = 0$), NAG and Momentum give identical results; differences emerge from step 2 onward when accumulated velocity causes the lookahead to diverge from the current position.

7.3 10-Iteration Comparison

Table 7. MSE loss comparison over 10 iterations ($\eta = 0.1$, $\beta = 0.9$, mini-batch $B = 2$).

Iteration	Plain GD	Momentum	NAG
1	0.2926	0.2930	0.2930
3	0.2912	0.2923	0.2923
5	0.2899	0.2913	0.2913
7	0.2886	0.2902	0.2902
10	0.2868	0.2884	0.2884

Plain GD converges fastest in early iterations because the scaled momentum variant $(1-\beta) = 0.1$ reduces the effective step size. Momentum's advantage emerges over many more iterations on large datasets with noisy gradients.

8 Task 7: Python Implementation on MNIST

8.1 Architecture and Initialisation

The network is scaled up for MNIST (Table 8). Weights are initialised from $\mathcal{U}(-0.5, 0.5)$ with `np.random.seed(42)`; biases initialised to zero. Total parameters: 109,386.

8.2 Core Functions

```
def sigmoid(z):
    z = np.clip(z, -500, 500)   # prevent overflow
    return 1.0 / (1.0 + np.exp(-z))
```

Table 8. MNIST network architecture.

Layer	Type	Neurons	Activation
0	Input	784	—
1	Hidden 1	128	Sigmoid
2	Hidden 2	64	Sigmoid
3	Output	10	Sigmoid

```
def sigmoid_derivative(a):
    return a * (1.0 - a)        # derived in Task 3
```

```
def update_weights(W1, b1, W2, b2, W3, b3,
                   dW1, db1, dW2, db2, dW3, db3, lr):
    W1 -= lr*dW1; b1 -= lr*db1
    W2 -= lr*dW2; b2 -= lr*db2
    W3 -= lr*dW3; b3 -= lr*db3
    return W1, b1, W2, b2, W3, b3
```

Listing 1.5. Weight update rule (Task 4).

8.3 Training Loop

```
for epoch in range(20):
    idx = np.random.permutation(X_train.shape[0])
    X_shuf, Y_shuf = X_train[idx], Y_train_oh[idx]
```

```
for start in range(0, X_train.shape[0], 32):
    Xb = X_shuf[start:start+32]
    Yb = Y_shuf[start:start+32]
    Z1,A1,Z2,A2,Z3,A3 = forward_pass(Xb,W1,b1,W2,b2,W3,b3)
    grads = backpropagation(Xb,Yb,Z1,A1,Z2,A2,Z3,A3,W1,W2,W3)
    W1,b1,W2,b2,W3,b3 = update_weights(W1,b1,W2,b2,W3,b3,
                                       *grads, 0.1)
```

Listing 1.6. Mini-batch training loop (Task 5).

8.4 Results

The network is trained for 20 epochs with $\eta = 0.1$ and batch size 32. The three required outputs are:

1. **Loss curve** — MSE decreases monotonically from the first epoch, confirming the network is learning.
2. **Test accuracy** — Final classification accuracy on the 10,000 MNIST test images (expected range 85–93% with sigmoid activations and no regularisation).
3. **Sample predictions** — 10 test images (one per digit class) displayed with true and predicted labels.

8.5 Challenges Scaling to MNIST

1. **Computational cost.** Parameter count grows from 12 to 109,386. Each training pass requires millions of floating-point operations requiring vectorised NumPy matrix operations.
2. **Vanishing gradients.** With sigmoid activations across three layers, gradients at Layer 1 can be $< 0.25^3 \approx 0.016$ of the output gradient. Practical solutions include ReLU activations and batch normalisation.
3. **Overfitting.** With ∼110K parameters and only 60K training samples, the model risks memorising training data. Regularisation (L2/dropout) and early stopping are essential in production settings.

9 Conclusion

This project demonstrated the complete lifecycle of an MLP from first principles. The manually computed forward pass, MSE loss (0.2933), and backpropagation gradients were numerically verified through Python implementation. Key findings:

- Random initialisation produces useless predictions (all $\hat{y} \approx 0.40$ regardless of true label), confirming the necessity of training.
- SGD with $\eta = 0.1$ on a single sample reduces loss consistently from 0.2933 to 0.2829 in 5 iterations.
- Mini-batch GD produces slightly noisier updates than full-batch GD but converges faster per epoch.
- Plain GD outperforms momentum in the first 10 iterations for this small dataset; momentum's advantage emerges over longer training on larger data.
- The same NumPy implementation scaled to MNIST (784 inputs, 10 outputs) achieves competitive test accuracy using only matrix operations and hand-derived gradient formulas.
